#### Exterminating the Fly

Flies may be combated by the following means:

I. The Fly Swatter .- This little instrument serves to kill many of the flies that pass by the screening.

II. Fly Paper.-This paper also serves to destroy a limited number dishes about the stable. It is not of flies.

III. Various Poisonous Solutions, -Such solutions are bichromate of potash (dram to 2 ounces of water) and 5 per cent solution of formalin in water. Various poisons found in the market in little tins supplied with wicks are also helpful. The water is added to the poison to be taken up by the wicks from which the fly sucks the poisoned water. When such poisons are used all open water poisoned water.

Fly Traps.—Such traps may be causes. Briefly, the sort of seed obtained in almost any hardware or department store, and should be placed about the house.

V. Fly Traps on Garbage Cans to be placed outside the Residences. -These traps are placed over a top of the can is made a little is so arranged that it will be surported from one-fourth to one-half inch above the rim of the can. This position of the top enables the fly to walk up the side of the can and to enter it. After feeding, the will pass into the trap. The traps cost only a few cents. Owing to the strong smell, the garbage can is thus converted into a most efficient fly trap. Every household, restaurant, grocery store, and meat shop should have such a garbage can. If a little meat is placed in the garbage can, the green blow fly will be caught along with the other flies.

If these cans were used in the places above designated, the adult fly population would soon be exterminated. The garbage can should be placed near the kitchen door convenient to the kitchen and to the garbage collector.

Business houses, especially those dealing in foodstuffs of any kind, should also have the ordinary plain fly traps in the front-and rear of the establishment. Livery barns and private barns should also be provided with traps which should land before plowing will surely be be placed near the manure pile.

VI. The destruction of the egg and the larvae of the fly, or the destruction of the breeding places of the fly. This is perhaps the most important factor in the extermination of this insect. Flies breed in dead vegetable and animal matter; consequently they breed in all trash about the house and yard. After the deposition of the eggs ten days elapse before the mature fly is developed; hence, all trash, both vegetable and animal, should be cleaned at intervals of less than ten days in order to destroy each crop of larvae. A general cleaning up should be done once each week -better twice.

VII. An ideal breeding place may be found in outhouses unprotected from flies; consequently all outhouses should be sereened, kept clean, and disinfected with chloride of lime.

VIII. Manure, on account of the decaying organic material, moisture, heat and fermentation, forms an ideal breeding place for flies. The manure should be removed twice a week. The area on which the manure is placed should be concreted. If the place is not concreted, after the manure is removed, it should be sprinkled with chloride of lime. A fly trap should be kept near this area. If the ma-

week, it should be kept in a screened shed so that flies can not gain access to it. The stable should be screened, kept free of manure, and should have in it a fly trap. The bichromate of potash above described should be placed in flat poisonous to animals or men.

The above recommendations should be carried out by every one in the community. An inspector should be appointed to see that all the yards, alleys, stables, stores, etc. are kept clean and supplied with fly traps which are maintained in a state of good repair.

#### Discing Corn Land Before Breaking

By J. C. HACKLEMAN.

The importance of a good seed should be removed from the room bed for corn is not sufficiently apso that the fly will have to drink preciated. A poor stand of corn may be due to a poor seed bed as IV. Various Types of Wire well as to inferior seed or other bed which is desirable for corn is one which is loosened deeply, from 6 to 8 inches, but which is well settled together below with a mellow and well pulverized surface.

One of the best ways to begin hole in the top of the can. The the preparation of such a seed bed is with a disc harrow before plowlarger in diameter than the can and ing. This is particularly true of stalk land, while the weighted disc will not only cut the stalks so they may be turned under, but it will also pulverize the surface so that when the soil is inverted, the organic matter which is thoroughdy will go to to the light coming ly mixed with the soil will not through the hole in the top and delay the reestablishment of cap-

The discing of stubble land is also important. Such discing will make the plowing at least a half horse easier and will provide for much more rapid decay of the stubble. Many men are coming to believe that the same can be said of sod land. Naturally much depends upon the season as to the best time for doing this. Fail discing or early winter discing on stalk land is usually preferable. Spring discing, however, is much more common and is preferable on stubble land.

With the present late spring, many men who have not already disced their corn land will fail to do it. Of course, no absolute rule can be laid down regarding this, but if dry weather should follow the present wet period, the man who takes time to disc his corn a gainer, as the soil will be prevented from becoming so compact and hard and will work up into a much better seed bed and the moisture conserved by such preparation may be needed before corn is mature.

There baving been so much in the papers recently about floods in other parts of the country, and remembering the exciting experiences here four years ago, quite a number of people got nervous when Grand river began to rise last week and moved into town, those not finding empty houses living in tents. The river after slopping over in the low places began to recede, and all is screne in the boftoms again.-Sumner Star.
